# Module 6: Introduction to Metropolis

Rebecca C. Steorts

knitr::opts\_chunk\$set(cache=TRUE)

## Agenda

- Motivation
- Markov chain Monte Carlo (MCMC)
- ► Hard Discs in a Box Example
- Metropolis Algorithm
- Example Applied to Normal-Normal
- ▶ Practice Excerise (Hoff 10.3)

# Intro to Markov chain Monte Carlo (MCMC)

Goal: sample from f(x), or approximate  $E_f[h(X)]$ .

Recall that f(x) is very complicated and hard to sample from.

How to deal with this?

- 1. What's a simple way?
- 2. What are two other ways?
- 3. What happens in high dimensions?

## High dimensional spaces

- In low dimensions, IS and RS works pretty well.
- ▶ But in high dimensions, a proposal g(x) that worked in 2-D, often doesn't mean that it will work in any dimension.
- ▶ Why? It's hard to capture high dimensional spaces!

Figure 1: A high dimensional space (many images).

We turn to Markov chain Monte Carlo (MCMC).

#### Intuition

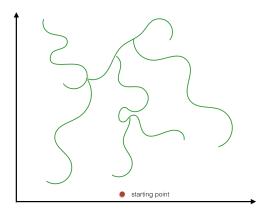

Figure 2: Example of a Markov chain and red starting point

#### Intuition

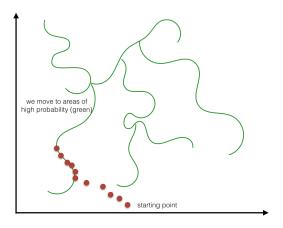

Figure 3: Example of a Markov chain and moving from the starting point to a high probability region.

#### What is Markov Chain Monte Carlo

- Markov Chain where we go next only depends on our last state (the Markov property).
- ► Monte Carlo just simulating data.

# The Markov property

Suppose that we have just visited states  $x_1, \ldots, x_{n-1}$ . The Markov property says the following:

$$P(X_n = x_n \mid X_1 = x_1, \dots, X_{n-1} = x_{n-1}) = P(X_n = x_n \mid X_{n-1} = x_{n-1}).$$

# Why MCMC?

- (a) the region of high probability tends to be "connected"
  - ► That is, we can get from one point to another without going through a low-probability region, and
- (b) we tend to be interested in the expectations of functions that are relatively smooth and have lots of "symmetries"
  - That is, one only needs to evaluate them at a small number of representative points in order to get the general picture.

# Advantages/Disadvantages of MCMC:

#### Advantages:

- applicable even when we can't directly draw samples
- works for complicated distributions in high-dimensional spaces, even when we don't know where the regions of high probability are
- relatively easy to implement
- ► fairly reliable

#### Disadvantages:

- slower than simple Monte Carlo or importance sampling (i.e., requires more samples for the same level of accuracy)
- can be very difficult to assess accuracy and evaluate convergence, even empirically

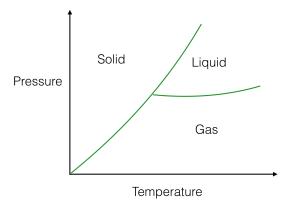

Figure 4: Example of a phase diagram in chemistry.

Many materials have phase diagrams that look like the picture above.

To understand this phenoma, a theoretical model was proposed: Metropolis, Rosenbluth, Rosenbluth, and Teller, 1953

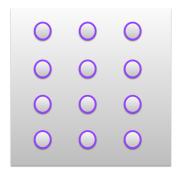

Figure 5: Example of N molecules (hard discs) bouncing around in a box.

Called hard discs because the molecules cannot overlap.

Have an X = (u, v) coordinate for each molecule.<sup>1</sup>

The total dimension of the space is  $\mathbb{R}^{2N}$ .

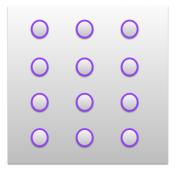

Figure 6: Example of N molecules (hard discs) bouncing around in a box.

 $<sup>^{1}\</sup>mathrm{For}$  the rest of the lecture, X will denote the two coordinate vectors of the molecule.

 $X \sim f(x)$  (Boltzman distribution).

Goal: compute  $E_f[h(x)]$ .

Since X is high dimensional, they proposed "clever moves" of the molecules.

Metropolis algorithm: For iterations i = 1, ..., n, do:

- 1. Consider a molecule and a box around the molecule.
- 2. Uniformly draw a point in the box.
- 3. According to a "rule", you accept or reject the point.
- 4. If it's accepted, you move the molecule.

Uniformly = pick a point at random with equal probability to all other points in the box

Consider a molecule and a box around the molecule.

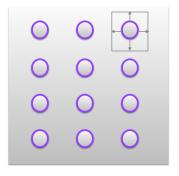

Figure 7: This illustrates step 1 of the algorithm.

Uniformly draw a point in the box.

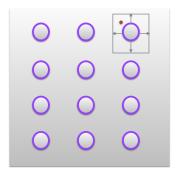

Figure 8: This illustrates step 2 of the algorithm.

According to a "rule", you accept or reject the point.

Here, it was accepted, so we move the molecule.

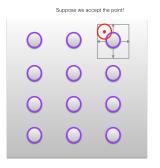

Figure 9: This illustrates step 3 and 4 of the algorithm.

Here, we show one entire iteration of the algorithm.

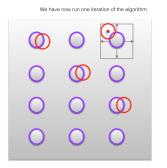

Figure 10: This illustrates one iteration of the algorithm.

After running many iterations n (not N), we have an approximation for  $E_f(h(X))$ , which is  $\frac{1}{n}\sum_i h(X_i)$ .

We will talk about the details later of why this is a "good approximation."

# Some food for thought

We just covered the Metropolis algorithm (1953 paper).

- We did not cover the exact procedure for accepting or rejecting (to come).
- $\triangleright$  Are the  $X_i$ 's independent?
- Our approximation holds by The Ergodic Theorem for those that want to learn more about it.
- The ergodic theorem says: "if we start at a point  $x_o$  and we keeping moving around in our high dimensional space, then we are guaranteed to eventually reach all points in that space with probability 1."

# Metropolis Algorithm

Setup: Assume pmf  $\pi$  on  $\mathcal{X}$  (countable).

Have  $f: \mathcal{X} \to \mathbb{R}$ .

#### Goal:

- a) sample/approximate from  $\pi$
- b) approximate  $E_{\pi}[f(x)], X \sim \pi$ .

The assumption is that  $\pi$  and or f(X) are complicated!

# Why things work!

Big idea and why it works: we apply the ergodic theorem.

"If we take samples  $X=(X_0,X_1,\ldots,)$  then by the ergodic theorem, they will eventually reach  $\pi$ , which is known as the stationary distribution (the true pmf)."

## Metropolis Algorithm

The approach is to apply the ergodic theorem.

- 1. If we run the Markov chain long enough, then the last state is approximately from  $\pi$ .
- 2. Under some regularity conditions,

$$\frac{1}{n}\sum_{i=1}^n f(X_i) \xrightarrow{a.s} E_{\pi}[f(x)].$$

# **Terminology**

1. Proposal matrix = stochastic matrix.

Let

$$Q=(Q_{ab}:a,b\in \mathcal{X}).$$

Note: I will use  $Q_{ab} = Q(a, b)$  at times.

2. Note:

$$\pi(x) = \tilde{\pi}(x)/z, z > 0.$$

What is known and unknown above? (Think back to rejection sampling)

## Metropolis Algorithm

- ▶ Choose a symmetric proposal matrix Q. So,  $Q_{ab} = Q_{ba}$ .
- ▶ Initialize  $x_o \in X$ .
- ▶ for  $i \in {0, 1, 2, ..., n-1}$ :
  - Sample proposal x from  $Q(x_i, x)$  if x is discrete, otherwise,  $p(x \mid x_i)$ .
  - ightharpoonup Sample r from Uniform(0,1).
  - ► If

$$r<rac{ ilde{\pi}(x)}{ ilde{\pi}(x_i)},$$

accept and  $x_{i+1} = x$ .

ightharpoonup Otherwise, reject and  $x_{i+1} = x_i$ .

Output:  $x_0, x_1, \ldots, x_n$ 

Comment: *r* is the rule for uniformly drawing a point in the box (slide 18).

## Metropolis Algorithm

Video that explains the correctness of the Metropolis Algorithm: https://www.youtube.com/watch?v=0j-Pq10U4LY&list=ULSc5hOS5HqdY&index=21

# Metropolis within a Bayesian setting

Goal: We want to sample from

$$p(\theta \mid y) = \frac{f(y \mid \theta)\pi(\theta)}{m(y)}.$$

Typically, we don't know m(y).

The notation is a bit more complicated, but the set up is the same.

We'll approach it a bit differently, but the idea is exactly the same.

## Building a Metropolis sampler

We know  $\pi(\theta)$  and  $f(y \mid \theta)$ , so we can can draw samples from these.

Our notation here will be that we assume parameter values  $\theta_1, \theta_2, \dots, \theta_s$  which are drawn from  $\pi(\theta)$ .

We assume a new parameter value comes in that is  $\theta^*$ .

#### Building a Metropolis sampler

Similar to before we assume a symmetric proposal distribution, which we call  $J(\theta^* \mid \theta^{(s)})$ .

- ▶ What does symmetry mean here?  $J(\theta_a \mid \theta_b) = J(\theta_b \mid \theta_a)$ .
- ► That is, the probability of proposing  $\theta^* = \theta_a$  given that  $\theta^{(s)} = \theta_b$  is equal to the probability of proposing  $\theta^* = \theta_b$  given that  $\theta^{(s)} = \theta_a$ .
- Symmetric proposals include:

$$J(\theta^* \mid \theta^{(s)}) = \frac{\mathsf{Uniform}(\theta^{(s)} - \delta, \theta^{(s)} + \delta)}{\mathsf{Uniform}(\theta^{(s)} - \delta, \theta^{(s)} + \delta)}$$

and

$$J(\theta^* \mid \theta^{(s)}) = \frac{\mathsf{Normal}(\theta^{(s)}, \delta^2)}{\mathsf{Normal}(\theta^{(s)}, \delta^2)}$$

#### Metropolis algorithm

The Metropolis algorithm proceeds as follows:

- 1. Sample  $\theta^* \sim J(\theta \mid \theta^{(s)})$ .
- 2. Compute the acceptance rule (r):

$$r = \frac{p(\theta^*|y)}{p(\theta^{(s)}|y)} = \frac{p(y \mid \theta^*)p(\theta^*)}{p(y \mid \theta^{(s)})p(\theta^{(s)})}.$$

3. Let

$$\theta^{(s+1)} = \begin{cases} \theta^* & \text{with prob min(r,1)} \\ \theta^{(s)} & \text{otherwise.} \end{cases}$$

Remark: Step 3 can be accomplished by sampling  $u \sim \text{Uniform}(0,1)$  and setting  $\theta^{(s+1)} = \theta^*$  if u < r and setting  $\theta^{(s+1)} = \theta^{(s)}$  otherwise.

Exercise: Convince yourselves that step 3 is the same as the remark!

#### A Toy Example of Metropolis

Let's test out the Metropolis algorithm for the conjugate Normal-Normal model with a known variance situation.

$$X_1, \ldots, X_n \mid \theta \stackrel{iid}{\sim} \mathsf{Normal}(\theta, \sigma^2)$$
  
 $\theta \sim \mathsf{Normal}(\mu, \tau^2).$ 

Recall that the posterior of  $\theta \mid X_1, \dots, X_n$  is Normal $(\mu_n, \tau_n^2)$ , where

$$\mu_n = \bar{x} \frac{n/\sigma^2}{n/\sigma^2 + 1/\tau^2} + \mu \frac{1/\tau^2}{n/\sigma^2 + 1/\tau^2}$$

and

$$\tau_n^2 = \frac{1}{n/\sigma^2 + 1/\tau^2}.$$

## Toy Example

In this example: 
$$\sigma^2=1,\, \tau^2=10,\, \mu=5,\, {\it n}=5,\,$$
 and 
$$x=(9.37,10.18,9.16,11.60,10.33).$$

For these data,  $\mu_n = 10.03$  and  $\tau_n^2 = 0.20$ .

Note: this is a toy example for illustration.

# Toy example

We need to compute the acceptance rule r.

$$r = \frac{p(\theta^*|x)}{p(\theta^{(s)}|x)} \tag{1}$$

$$=\frac{p(x|\theta^*)p(\theta^*)}{p(x|\theta^{(s)})p(\theta^{(s)})}$$
(2)

$$= \left(\frac{\prod_{i} \operatorname{dnorm}(x_{i}, \theta^{*}, \sigma)}{\prod_{i} \operatorname{dnorm}(x_{i}, \theta^{(s)}, \sigma)}\right) \left(\frac{\operatorname{dnorm}(\theta^{*}, \mu, \tau)}{\operatorname{dnorm}(\theta^{(s)}, \mu, \tau)}\right)$$
(3)

#### Toy example

In many cases, computing the rule r directly can be numerically unstable, however, this can be modified by taking  $\log r$ .

This results in

$$\frac{\log r}{\log r} = \sum_{i} \left[ \log \operatorname{dnorm}(x_{i}, \theta^{*}, \sigma) - \log \operatorname{dnorm}(x_{i}, \theta^{(s)}, \sigma) \right] + \left[ \log \operatorname{dnorm}(\theta^{*}, \mu, \tau) \right] - \log \operatorname{dnorm}(\theta^{(s)}, \mu, \tau).$$

Then a proposal is accepted if  $\log u < \log r$ , where u is sampled from the Uniform(0,1).

#### Toy example

We generate 500 iterations of the Metropolis algorithm starting at  $\theta^{(0)}=0$  and using a normal proposal distribution, where

$$\theta^{(s+1)} \sim \mathsf{Normal}(\theta^{(s)}, 1).$$

We will then generate 10,000 iterations since 500 will not be sufficient.

Figure~12 shows a traceplot for this run as well as a histogram for the Metropolis algorithm compared with a draw from the true normal density.

#### Traceplot

What is a traceplot? A traceplot is a convergence diagnostic.

It's a plot of the parameter of interest versus the number of MCMC iterations.

What does it tell us?

- 1. It can tell us when we have not run our MCMC long enough.
- 2. It can tell us when we migth be in a situation of multimodality (we will see this in future lectures).
- 3. If the plots looks stable, then it tells us that we do not see anything to warrant issues with a lack of convergence of the chain.

What does it not tell us?

It cannot tell us that our MCMC has converged!

#### Code

```
# setting values
set.seed(1)
s2<-1
t2<-10
mu < -5;
n<-5
# defining the data
x < -c(9.37, 10.18, 9.16, 11.60, 10.33)
# mean of the normal posterior
mu.n < -(mean(x)*n/s2 + mu/t2)/(n/s2+1/t2)
# variance of the normal posterior
t2.n<-1/(n/s2+1/t2)
```

```
\#\#S = total \ num \ of \ simulations
theta<-0; delta<-1; S<-50; THETA<-NULL
for(s in 1:S){
## simulating our proposal
theta.star<-rnorm(1,theta,sqrt(delta))
##taking the log of the ratio r
log.r<-( sum(dnorm(x,theta.star,sqrt(s2),log=TRUE)) +</pre>
dnorm(theta.star,mu,sqrt(t2),log=TRUE) ) -
( sum(dnorm(x,theta,sqrt(s2),log=TRUE)) +
dnorm(theta,mu,sqrt(t2),log=TRUE) )
if(log(runif(1))<log.r) {</pre>
  theta<-theta.star
THETA<-c(THETA, theta) ##updating THETA

### Traceplot and Histogram

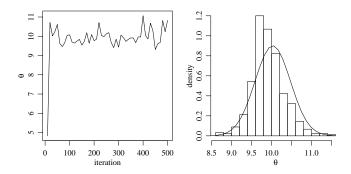

Figure 11: Left: trace plot of the Metropolis sampler. Right: Histogram versus true normal density for 500 iterations.

# Traceplot and Histogram

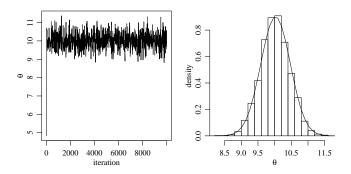

Figure 12: Left: trace plot of the Metropolis sampler. Right: Histogram versus true normal density for 10,000 iterations.

#### Traceplot

Given that we have looked at n = 500 iterations of the Metroplis sampler, does it seem that our approximation is a good one?

What about n = 10,000 iterations?

#### Questions you should be able to answer!

- What is the goal of Metropolis?
- ▶ What is known and unknown?
- ► What are good proposals?
- What does the ergodic theorem say in words?
- Are good proposals always easy to choose?
- When would we use Metropolis over Importance sampling and Rejection sampling?
- What is a simple diagnostic of a Markov chain?
- Are we guaranteed convergence of the Markov chain?

### **Detailed Takeways**

- Monte Carlo is not sufficient for high dimensions
- Intuitive of MCMC
- What is Monte Carlo
- ► What is a Markov Chain
- ▶ What is the memoryless property
- Why do we use MCMC
- Advantages versus Disdavantages of MCMC
- ▶ Metropolis et al. (1953) original paper and understanding this case study
- Ergodic Theorem
- ► Metropolis Algorithm (from the 1953 paper)
- Metropolis Algorithm in a Bayesian setting
- Normal-Normal Example using Metropolis
- Traceplots: What they tells us and what they don't tells us
- How long should you run an MCMC chain
- How you would walk through a case study of metropolis but on the normal-uniform model (very similar to the in class study)

#### Information about Markov chains

If you're wondering what a Markov chain and a problem looks like in a discrete space, take a look at this video:

https://www.youtube.com/watch?v=i3AkTO9HLXo

If you're wanting to read more about Markov chains, see http://faculty.washington.edu/yenchic/18A\_stat516/Lec3\_DTMC\_p1.pdf
